Review on Emerging and Re-Emerging Zoonotic Viral Diseases, Future Challenges and Strategies for Sustainable Tackling

Sherif Mohammed*

A Paper Submitted to the College of Veterinary Medicine for the Course Seminar on Animal Health (CLIS 682), College of Veterinary Medicine, Haramaya University, Advisor: Henok Ayalew (DVM, MSc, MPH, Asst. Prof.).

Abstract

Emerging and re-emerging zoonoses are still remaining a leading cause of high morbidity and mortality in many countries of the world. These diseases constitute the major threats to human health; and are caused by a large number of organisms. The incidence of emerging infectious diseases in humans has increased within the recent past or threatens to increase in the near future. Over 30 new infectious agents have been detected worldwide in the last three decades; 60 per cent of these are of zoonotic origin. The emerging and re-emerging infectious diseases and their basic causes present a threat to the stability of the nations worldwide. The factors for the emergence/re-emergence of infectious diseases are complex and interrelated. The emergence and re-emergence of several zoonotic diseases in the past require a systematic surveillance and evaluation of disease control programme. Subsequently, the involvement of the Veterinarian and Public Health professionals in the process of global health programme is highly imperative.

Keywords: Emerging disease; Re-emerging disease; Viral diseases; Zoonoses.

Introduction

Zoonosis is most commonly defined as any disease and/or infection which are naturally transmissible from vertebrate animals to man [1]. Emerging infectious diseases are those infections, in which the incidence of humans and animal have either increased during the last two decades or threaten to increase in the near future. This term includes newly appearing infections or those spreading to new geographical areas. It also refers to those diseases which were easily controlled previously by antimicrobials but have developed new resistance to different drugs. Re-emerging infectious diseases are those that have reappeared after a significant decline in their incidence. These include virus such as Zika virus, Nipah virus, Ebola virus, West Nile virus, H5N1 Avian influenza, Rift valley fever, and the like, bacteria such as Typhoid fever, Diphtheria, Hepatitis C, etc and protozoa, are some of common zoonotic pathogens [2].

A literature survey identified 1,407 species of human pathogens, with 177 (13%) species regarded as emerging or re-emerging. Distribution of these pathogens by groups shows that 37 per cent of emerging and re-emerging are viruses and prions followed by protozoa 25 per cent [3]. Viruses with RNA as their genetic material can quickly adapt and exploit these varying conditions because of the high error rates of the virus enzymes (polymerases) that replicate their genomes. This indicates that emerging and re-emerging pathogens are disproportionately viruses [4]. However, a complex interplay of factors can influence disease emergence and re-emergence. This often follows ecological change caused by human activities such as agricultural changes, urbanization, migration, deforestation and dam building. In addition, international travel, break down of public health measures and microbial adaptation also led to the emergence of the zoonotic diseases [5].

The emerging and re-emerging infectious diseases account for 26 per cent of annual deaths worldwide [6,7]. The burden of morbidity and mortality associated with infectious diseases falls most heavily on people in developing countries, and particularly on infants and children about three million children death each year from malaria and diarrhoeal diseases alone [8]. Future occurrences of newly emerging and re-emerging diseases are most likely to erupt at these intensifying interfaces. In less developed countries, the communities most likely to be affected by such outbreaks are, those that are poor or in less accessible areas. Such community’s frequently rely on inadequate methods of medical surveillance and diagnostics, as well as traditional treatment methods. As the result, it is unfortunately quite likely that an emerging disease with high epidemic potential may only be detected after it has become established in humans or their livestock and has already spread significantly [9].

Therefore, this review aims:

- To provide highlights on some of emerging and re-emerging viral zoonotic diseases
- To review factors of emergences and re-emergences of these diseases and
- To insight sustenabale prevention and control strategies for these diseases

**Literature review**

**Emerging zoonotic viral diseases**

**Zika virus**

Zika is a mosquito-transmitted virus that has spread broadly in tropical regions and caused epidemics, especially in the past 8–9 years. In its native range in West Africa and Uganda, Zika virus is maintained in forest cycles between infected tree hole mosquitoes and arboreal primate hosts, with human infections regarded as incidental and medically inconsequential [10].

In the invasive range of the virus outside of Africa, the most likely vector of Zika is Aedes aegypti, first recognized as infected in nature in Malaysia. The preference of this domestic Aedes aegypti for feeding on human hosts in tropical cities overrides its inefficiency in developing the ZIKV [11]. The other is Aedes albopictus which has been implicated as a Zika vector in Gabon and has expanded its invasive range worldwide [12]. Evidence of Zika in Pakistan, Malaysia, and Indonesia indicated that Zika became established in Asia, perhaps around Island, Micronesia, which resulted in 2007 in the first epidemic attributable to this virus [13,14]. This Asian lineage was believed to be the source of an introduction of Zika to Yap Island, Micronesia, which resulted in the first epidemic in 2007 attributable to this virus [13].

A larger outbreak of Zika in French Polynesia during 2013, also derived from the Asian lineage, followed the epidemic in Yap [15]. An epidemic in north eastern Brazil in early 2015 is suspected to have begun with the introduction of Zika by a traveler from French Polynesia [16,17]. More than twenty countries in the tropical Americas, as well as the Common wealth of Puerto Rico and the US Virgin Islands, currently recognize active ZIKV transmission [18].

![Figure 1: Proposed directional movement of Zika virus within Africa and through its invasive ranges source [14].](image)

According to [11], it has great importance because both the mosquito and Zika virus are extending their range and thus it is possible that human-feeding populations of this vector species may co-occur with the emergent virus [13]. Until recently illnesses from ZIKV have been classified as clinically mild with symptoms lasting several days to a week, with many infected individuals being asymptomatic (80%) [18]. Hospitalizations and fatalities were uncommon. However, the 2013 ZIKV outbreak in French Polynesia implicated ZIKV in neurological complications resulting in Guillain-Barré syndrome, and the recent ZIKV outbreak in Brazil is associated with an increase in the number of babies born with microcephaly [19,20].

**Avian influenza**

Avian influenza or bird flu, caused by the highly pathogenic H5N1 influenza virus has affected at least eight countries in Asia leading to outbreaks of severe disease, mass deaths and destruction of chickens. The virus that caused such destruction is known to have the capacity to be transmitted from infected chickens to cause severe disease and high mortality in humans [21].

The evolution of influenza is a continuing process and the increase the emergence of the highly pathogenic to both veterinary and public health. Highly concentrated poultry and pig farming in conjunction with traditional animal farming provide optimal condition for increased mutation, re-assortement and recombination of influenza virus [20].

The emergence and re-emergence of influenza viruses with pandemic potential for both human and veterinary public health is of great concern to humans globally. Especially, the convergence of factors affecting contemporary human and animal health issues has led to changing roles for veterinarians and public health officials worldwide [22].
Ebola virus

Ebola viral disease has drawn international attention after a recent outbreak in West Africa [23]. It was first recognized in 1976 when 2 unrelated outbreaks occurred in southern Sudan and the Democratic Republic of the Congo [24]. Including the present epidemic, there have been approximately 20 recognized outbreaks of Ebola, all occurring in Africa, with fatality rates of 25% to 90% [25].

The recent Ebola outbreak that began in March 2014, initially announced by the Centers for Disease Control and Prevention (CDC) on March 25th, is the largest in history [18]. It is associated with a new strain of Zaire species, the most deadly of the 5 Ebola species, with a reported case fatality rate of approximately 55% [26]. According to the CDC, as of September 30, 2014 (the most recent information available at this article’s writing), there have been 6,574 total cases (3,626 were laboratory confirmed) across 5 countries (Guinea, Liberia, Nigeria, Senegal, and Sierra Leone) and 3,091 suspected case deaths [18]. Figure 1 shows a map of the West African countries affected by the outbreak [18].

Rift valley fever

Rift Valley Fever (RVF) is an important, neglected, zoonotic, mosquito-borne viral disease that causes severe human illness and death, as well as significant economic losses in the livestock industry. The disease is caused by RVF virus (RVFV), an arbovirus of the Bunyaviridae family [25]. The virus is known to infect different animal hosts, particularly sheep, cattle, and goats. Infection by RVFV usually spreads in animals first via mosquito bites [20]. From animals, the virus is transmitted to humans through direct contact, such as contact with the raw products or secretions of infected animals [31]. The virus can also be transmitted by aerosols from blood and other infected body fluids, and infections are frequent among virologists, veterinarians, and slaughter house workers [32,33].

Recent RVF outbreaks have been characterized by severe infection and death in humans, with a high Case-Fatality Rate (CFR) of 50% for the hemorrhagic syndrome form. This outbreak in East African (Tanzania, Kenya, and Somalia) caused 478 human deaths in 1998 and 309 in 2007 [25,1,34]. In Saudi Arabia, the first recorded outbreak occurred in 2000, resulting in 883 human cases with 124 deaths (CFR 14%), and 1,328 human cases and 166 deaths in neighboring north western Yemen. During the 2007 outbreak in Sudan, 698 cases and 222 deaths were recorded. It is clear that the epidemiological pattern of recent RVFV outbreaks has changed to resulting in more severe illness and high fatality rates among humans [35].

In addition, the disease can result in negative consequences to the livestock, and other sectors of the economy. For example, the 2006/2007 RVFV outbreak resulted in losses of over 60 million USD, equivalent to the annual value of livestock trade between East African countries. The 2007 outbreak in Sudan led to bans on livestock exports to Saudi Arabia, which had a massive economic impact on trade between the two countries [35].

West nile virus

West Nile Virus (WNV) is re-emerging pathogen whose ecology and epidemiology span the multidimensional interface between viral pathogen, invasive arthropod disease vectors, wildlife, domestic animals and human beings [36]. It is a neurotropic flavivirus that is endemic in many parts of the world. As an arbovirus, WNV is transmitted by mosquitoes between birds and mammals.

More than 100 different mammalian species, including many species of bats, have been shown to be susceptible to WNV infection [37], and further increasing the risk of emergence via the close proximity of animal and human populations. It is first isolated from a febrile patient in Uganda in 1937, and was introduced into North America in 1999, resulting in a large outbreak
and rapid spread from the East Coast to the West Coast in a very short period.

Most (~80%) human infections are subclinical, symptomatic infections range from a self limiting fever to severe neurological disease, long-term sequelae and death [36]. The year 2012 saw a new wave of WNV outbreaks in the USA, with the second-highest number of WNV cases on record. High numbers of WNV cases were also reported in Europe in the same year, with 224 cases in the European Union and 538 additional cases in neighbouring countries. Epidemiologists suspect that a combination of the presence of wild birds, increased mosquito populations and favourable weather conditions in the USA and Europe are the key drivers for these outbreaks [38].

Factors for emergence and re-emergences of zoonotic viral diseases

The complex interaction between environment/ecology, social, health care, human demographics and behavior influences the emergence and re-emergence of zoonotic viral diseases [39,40]. Some of the critical factors that were contributing to the emergence and re-emergence of zoonotic diseases are discussed bellow [3].

International travel and trade

The ever increasing world population and migration of masses in search of job to urban areas, lead to overcrowding, inadequate sanitation and hygiene, which provide an ideal breeding ground for infectious agents. Increased international travel, especially without taking appropriate vaccine and other protective measures, lead to increased infection in travellers, who subsequently bring the infection back own homes on their return. In addition to human movements, increased cross-border trade of livestock and wildlife is also a concern [21]. Trading centres, for example, can act as mixing bowls for humans and dozens of other species before they are shipped to other markets, sold locally, or even freed and sent back into the wild [48].

Globalization

The phenomenon of globalization has been one of the most remarkable changes in our lives over the last quarter of a century. Globalization has been the driving force that has profoundly impacted international trade, economics and cultural interactions. The spatial mobility of the average human has increased more than 1,000 folds since 1800. At the turn of this century almost 1 billion people travelled internationally and this number is expected to rapidly [49]. Not only are more people travelling, but travel is faster and more culturally widespread and permeates into areas of the world not readily accessible in the past. People, animals and products can circumvent the globe faster than the incubation period of almost every pathogen known today [3].

Microbial adaptation

In addition to the climatic conditions, international travel, globalization, trade, demographic change and environmental factors, which can drive the emergence of novel diseases and increase the incidence, prevalence, or geographic scope of existing ones, the importance of public health system factors as influences, in particular for the emergence of newly resistant strains, should not be underestimated [48]. Microbes are especially competent at adaptation and change under selective pressures for survival and replication. The remarkable adaptation of microbes to become resistant to antimicrobial products is seen in both human and animal populations and is linked between the two [3].

Future challenges of emerging and re-emerging zoonotic viral diseases

Emerging and re-emerging zoonotic diseases are responsible for profound political, social, and economic impacts on society. Despite extraordinary progress during the past two decades,
infectious diseases still kill 15 million people each year, and deadly new diseases continue to emerge and re-emerge [4]. We have recently entered a new epidemiologic era in which these diseases are showing an upward trend and their global effect is unprecedented. In relation with this approximately 75% of the new infectious diseases in humans are zoonotic; thus, the veterinary profession and animal health officials are faced with immense challenges, from these zoonoses. A literature survey identified 1,407 species of human pathogens, with 177 (13%) species regarded as emerging or re-emerging [40].

The world in which we live and work is growing progressively interdependent and complex. Unfortunately, this interdependence and complexity is also creating new factors to ensure that emerging and re-emerging diseases will continue to have significant effects on human and animal health as well into this century. The OIE and animal health officials worldwide are experiencing the impact of emerging zoonoses and clearly believe that these diseases and countries’ responses will be a much more important part of the future [40].

The World Health Organization has warned that the source of the next human pandemic is likely to be zoonotic and that wild life is a prime culprit [20]. While the current list of known EIDs is a major concern, it is the unknown EIDs out there, with a potential for efficient animal-to-human transmission that may pose the biggest threat. Over the past decade there have been a number of epidemics, raising the concern that they are precursors to a pandemic [50].

Over the past century, the emergences of numerous zoonotic infections have resulted in varying degrees of human fatalities. For instance Influenza viruses originating from birds account for an important portion of these deaths and recently many new zoonotic viruses originating in bats, such as Hendra virus, Nipah virus, and severe acute respiratory syndrome corona virus (SARS-CoV), have caused outbreaks with high mortality rates [50].

Research, education (training and technology transfer), and information/communication [52].

Recognition

Emerging zoonoses need first to be identified. Usually, identification follows recognition of a health problem in the human population and too often only later in the domestic animal or wildlife population, despite the fact that clinical manifestations may have occurred first in the animal reservoir, as illustrated by recent outbreaks of Rift Valley fever, Q fever. A new approach should be to investigate health problems concomitantly in animals and humans or to identify health problems in animals that could be associated with human disease. The recent outbreaks and spread of West Nile virus in Europe and Northern America fully support such a strategy. Furthermore, we need to start an inventory of potential pathogens harboured by free-ranging wildlife like that of the exploration of Hendra virus outbreaks indirectly led to the identification of a rabies virus variant in Australian pteropod bats [53].

Investigation and collaboration

A new approach to investigating new or emerging zoonotic agents is to conduct an inventory of pathogens carried by various wildlife species, especially those that encroach on human habitat. The collaborative fieldwork of multidisciplinary teams with the support of expert staff scientists and laboratories with advanced molecular biology and immunology techniques is essential to conduct investigations of new and emerging zoonoses. However, initial work is still heavily dependent on field recognition of health problems in animals and/or the human population. Well-trained field epidemiologists, ecologists, and environmentalists, especially those with a veterinary background, will be key players in such an endeavour. There is a strong need for interdisciplinary collaborations in identifying new zoonotic agents. Such collaborative efforts led to the identification of new arena viruses in North America [54]. Collaboration at the local level among different institutions or organizations concerned with human health, animal health, and wildlife health is also a key factor for investigating and identifying emerging zoonoses [53].

Advanced structures for diagnosis and surveillance

The prevention and control of emerging zoonoses require even more sophisticated diagnostic tools than before. Investigators at the local level need to have access to reference laboratories fully equipped with molecular biology tools. In a not-so-distant future, one can hope that microchip kits will allow for instantaneous diagnosis of several organisms at the site of investigation. Such progress will be essential for timely surveillance and detection of outbreaks in animal and human populations. Such a technology cannot be developed without

Figure 4: Global burdens of Emerging zoonoses [50]. The emerging and re-emerging zoonoses also resulted in huge financial losses in many countries of the world including developing country.

Strategies for prevention and control of emerging and re-emerging zoonotic viral diseases

In order to prevent and control emerging zoonoses, several major steps need to be taken, including recognition, investigation, and collaboration, the development of advanced structures for diagnosis and surveillance, international and interdisciplinary interventions, applied epidemiological and ecological
major international collaboration, especially between developed countries that have the resources and the know-how, on the one hand, and developing countries, where many of these emerging pathogens are endemic, on the other. It is in the interest of developed countries to protect themselves by investigating possible sources of infection in their natural environment and where human exposure might be at the highest level [53].

Education and training

The need for training of professionals in the field of zoonotic diseases is an emergency. Medical knowledge has to be extended to those who may see the first animal or human cases of zoonoses. Similarly, training in molecular epidemiology will allow to better understand the diversity of the pathogens involved and the specificity of their reservoirs and to enhance ability to control these infections [53].

Communication/information

Finally, a proper strategy for prevention and control relies on accurate and timely dissemination of information concerning new emerging diseases. Specialized sites in the internet system are other very important communication and information tools that have been developed in recent years. They will be very useful for the dissemination of prevention and control measures, as is illustrated by the Centers for Disease Control Web site (www.cdc.gov), where all control measures for hantavirus infection control are fully access to the public [52].

Conclusion and recommendations

Emerging and re-emerging diseases have caused devastating effects internationally, with millions infected and billions spent. Some diseases have become pandemic, spreading from one continent to another causing massive mortality rates and affecting global economies and livelihoods. Changes in pathogens and/or their vectors appear to have expanded their geographic or host range as a result of global warming and other associated climatic changes. Other contributing factors may include habitat changes caused by humans; the complex interaction between environment/ecology; spread of antimicrobial resistance; globalization and trade; international travel; human demographics and behavior influences the emergence and re-emergence of zoonotic viral disease. Therefore, based on these facts, the following recommendations are forwarded:

- There is need to develop epidemiology at the ground such as community level.
- Keeping the natural environment from disasters and struggling against global warm to keep the globe safe for mankind.
- Since no one knows what new diseases will emerge and what old ones will re-emerge, the public health system and preparedness plan must be strengthened.
- Since zoonosis can infect both animal and humans, the medical and veterinary communities should work closely together in clinical, public health and research settings.

Acknowledgement

- Praise to Allah, the most Gracious, merciful and self-sufficient master. I would like to express my heartfelt gratitude and respect to my advisor Dr. Henok Ayalew for his remarkable support, scholarly guidance, valuable comments, and in fact, constructive critics of the manuscript.
- My special thanks goes to my family members; my beloved mother Shukria, my father Mohammed, my wife Arafo, my brothers and sister who directly or indirectly helped me in unlimited financial support and encouragement.
- I am extremely grateful to my colleagues and my entire dorm mates for their help and moral support.
